

Description

- 5 Title of the invention: Housing for receiving a component
which can be connected to the housing in a pluggable manner.

The invention relates to a housing for receiving a component
which can be connected to the housing in a pluggable manner,
in particular an optoelectronic transceiver, according to the
precharacterizing clause of claim 1.

It is known to arrange optoelectronic transceivers on a
printed-circuit board and connect them to an optical network
by means of optical plug-in connectors. Known in particular
are so-called small-form-factor-pluggable (SFP) transceivers
of a small type, which are of a pluggable design (so-called
"detachable transceivers") and can be plugged into a
receptacle of a housing mounted onto the printed-circuit
board.

A corresponding housing 1 is represented in Figure 5. The
housing comprises an upper part (top cage) 22 and a lower part
(bottom cage) 21, which can be connected to each other in an
engageable manner and form a receiving housing into which a
transceiver can be plugged or from which a transceiver can be

unplugged in the direction of the double-headed arrow A-B. At the same time, the housing 1 preferably serves as a shielding plate for the electromechanical shielding of the pluggable transceiver.

5

The lower part 21 of the housing is fastened on a printed-circuit board 3. Both parts of the housing 21, 22 protrude through a cutout in a metallic rear wall (not represented), which is electrically connected to the housing via contact springs 11. Also mounted within the housing and directly on the printed-circuit board 3 is an electrical plug 4, by means of which the plugged-in transceiver can be connected to the printed-circuit board 3 and into which the transceiver is inserted during plugging into the housing 1.

During plugging of a transceiver into the housing 1, rectangular pressing springs 51, 52 formed in the region of the rear end face of the lower part 2 of the housing are prestressed. Locking of the transceiver in the housing takes place by means of a locking clip 6, which is formed in the front region of the lower part 2 of the housing and into which a locking lug of the transceiver can engage. During unlocking of the transceiver by pressing down of the resiliently formed fastening clip 6, the transceiver is pressed out of the housing 1 by the prestressed pressing springs 51, 52. The

rectangular ejecting springs 51, 52 are represented in front view in Figure 6.

A disadvantage of the known housing is that the spring forces achieved by stressing of the pressing springs 51, 52 are not adequate to ensure in a dependable way that the transceiver is pressed out of the housing 1 when it is unlocked. In particular, the transceiver is pressed only a small distance out of the housing on account of frictional forces between the housing and the transceiver during unlocking.

The present invention is based on the object of providing a housing for receiving a component which can be connected to the housing in a pluggable manner which ensures that the component is dependably and reliably pressed out of the housing when it is unlocked.

This object is achieved according to the invention by a housing with the features of claim 1. Preferred and advantageous developments of the invention are specified in the subclaims.

Accordingly, it is provided according to the invention that at least one pressing spring of the housing is designed in such a way that it tapers in its width in the direction of the interior of the housing. A spring form of this type has the advantage that higher spring forces can be realized with it: the restoring force or spring force is greater than in the case of a rectangular design of the pressing spring known in the prior art. This results from a more uniform bending stress of the spring material which accompanies the reduction in the width of the spring in the direction of the interior of the housing. In particular, the tapering spring bends in a form approximating that of a circle, while a rectangular spring bends in the form of a parabola. However, circular bending entails a higher amount of spring work and energy storage.

A further advantage of using a spring tapering in its width is that less space is taken up by the spring inside the housing. One result of this is the possibility of extending the length of the spring in the direction of the interior of the housing, allowing for example the end of the spring to protrude beyond an electrical plug arranged in the housing. By extending the length of the spring, higher spring forces can also be realized. Another result is the possibility of making an electrical plug arranged in the housing or other components

arranged in the housing larger and consequently easier to handle.

In a preferred development of the invention, the pressing
5 spring is of a trapezoidal design. The two parallel sides of
the pressing spring in this case run parallel to the lateral
walls of the housing. On account of the tapering of the
pressing spring in the direction of the interior of the
housing, the parallel side running in the interior of the
10 housing has a smaller width than the side running along the
wall of the housing. A trapezoidal design of the spring has
the advantage that it is simple to produce, since the
corresponding edges of the metal plate can be worked in
straight lines.

15 It is likewise within the scope of the invention for the
pressing spring to be of a triangular or else parabolic
design. In the case of a triangular design, it is preferred
to provide the form of an isosceles triangle, the base of
20 which runs along the wall of the housing and the corner of
which, formed by the equal sides, lies in the interior of the
housing. Similarly, in the case of a parabolic design of the
pressing spring, the inflection point of the parabola lies in
the interior of the housing.

In the preferred embodiment, the pressing spring is designed as a rear continuation of the plate of the housing, with respect to the plugging-in direction of the component, bent around by more than 90° into the interior of the housing.

- 5 This is a simple way of providing an integral design of the spring with the housing which can be easily produced.

The housing is preferably designed in such a way that it has an upper part and a lower part, which can be connected to the printed-circuit board. The pressing spring is in this case preferably articulated on the lower part.

Preferably, two pressing springs are articulated on the right-hand and left-hand walls of the housing in a symmetrical arrangement, to be precise in each case in the upper region of the wall of the housing. This ensures that the pressing springs are freely accessible and are not concealed by other components arranged in the housing, such as a plug connected to the printed-circuit board.

The legs of the pressing spring articulated on the housing preferably terminate flush with the upper edge of the housing. This provides a maximum size of the spring toward the upper edge of the housing.

The invention is explained in more detail below on the basis of several exemplary embodiments with reference to the figures of the drawing, in which:

5 Figure 1 shows a perspective view of a lower part of the housing according to the invention;

Figure 2 shows a front view of the housing of Figure 1;

10 Figure 3 shows a first alternative design of a pressing spring according to the invention;

Figure 4 shows a second alternative design of a pressing spring according to the invention;

15 Figure 5 shows a perspective representation of a housing known in the prior art and

Figure 6 shows a front view of the housing of Figure 5.

20 The housing according to the prior art was explained at the beginning on the basis of Figures 5 and 6.

Figure 1 shows the lower part 21 of a housing according to the invention, which can be connected to an upper part of the housing according to Figure 5 by means of locking clips 21a.

Downwardly protruding fastening pins 21b serve for fastening the housing on a printed-circuit board (not represented). The bottom of the lower part 21 of the housing has in the rear region a clearance 8, in which an electrical plug corresponding to the plug 4 of Figure 5 is fastened on the printed-circuit board.

In the front region of the lower part 21 there is formed, in turn, a locking clip 6, which serves for the locking of a transceiver plugged into the housing.

The housing according to Figures 1, 2 differs from the known housing of Figure 5 essentially by the design of the pressing or ejecting springs. For instance, formed onto the rear edge 21c of the lateral walls 211, 212 of the housing are two pressing springs 71, 72 which have a trapezoidal form. This can be seen in particular in the front view of Figure 2. In this case, according to Figure 2, each pressing spring 71, 72 has essentially parallel sides 71a, 71b and 72a, 72b, respectively, of which the longer side is in each case articulated on the lateral wall 211, 212 of the housing. The two other sides 71c, 71d and 72c, 72d, respectively, do not run parallel, the upper side 71c, 72c terminating flush with the upper side of the lateral wall 211, 212 of the housing and extending in the transverse direction at right angles with respect to said wall.

1 The width of the pressing springs 71, 72, reducing in the
2 direction of the interior of the housing, is represented in
3 Figure 2 in the case of one pressing spring 72 by way of
4 example by two widths B1, B2.

5 The trapezoidal ejecting springs 71, 72 are integrally formed
6 with the wall 21 of the housing and designed as continuations
7 of the wall of the housing which are bent around by more than
8 90° into the interior of the housing to produce a spring
9 effect.

10 A transceiver is pushed in the direction A into the lower part
11 21 of the housing or the pushing-in opening into the housing
12 formed by the upper part of the housing and the lower part of
13 the housing. The front edges of the transceiver thereby come
14 into contact with the lateral edges 71a, 72a of the pressing
15 springs 71, 72 and press them away toward the rear, thereby
16 creating a prestressing effect. After locking of the
17 transceiver by means of the locking clip 6, the transceiver is
18 locked in the housing under prestress.

19 When the locking clip 6 is actuated, the pressing springs 71,
20 72 are relieved and they press the transceiver out of the
21 housing.

Given the same plate thickness and the same leg height, the restoring force or ejecting force provided by the restoring springs 71, 72 is in this case greater in the region of the wall 21 of the housing than when the rectangular pressing springs are used. This is to do with the fact that there is an approximately equal bending stress of the spring material in every cross section of the spring on account of the decreasing width of the springs in the direction of the interior of the housing.

The housing and the pressing springs preferably consist of a metallic material, in particular of metal plate. In applications in which an electromagnetic shielding of the component inserted into the housing is not required or is provided by other structures, the use of a non-metallic material is also conceivable however. It is also conceivable, for example, to produce the housing from plastic and to form metallic restoring springs on it.

An alternative configuration of a pressing spring according to the invention is represented in Figure 3. According to this, the pressing spring 73 is of a triangular design, one corner 73a protruding into the interior of the housing.

In Figure 4, the pressing spring 74 is of a parabolic design, the inflection point 74a lying in the interior of the housing.

The invention is not restricted in its execution to the
exemplary embodiments represented. All that is essential for
the invention is that at least one pressing spring which
5 tapers in its width in the direction of the interior of the
housing and serves for the resilient reception of a component
is provided in the interior of the housing.
